

Truth- $x \rightarrow$ reco- x migration, charm events. Dashed = perfect; dotted = the $x \geq 0.2$ and 0.4 signal cuts.
Lepton-only shows almost NO correlation — x information is destroyed. Σ retains a clear diagonal.

Large- x signal retention, $x \geq 0.2$. Σ is flat in σ_{θ_h} (it uses $E + p_z$) AND unaffected by E_{in} (it reconstructs it).
If the incoming muon is not measured — only a downstream spectrometer — lepton-only and double-angle are not available at all.

vs hadronic angular resolution

vs whether the incoming muon energy is measured
